ABSTRACT

This study examines trajectory profiles of University students over the course of a University semester defined based on global levels of psychological need satisfaction, as proposed by self-determination theory (SDT). This study also documents the Implications of these trajectories for a variety of educational outcomes. A sample of 461 first-year undergraduates completed all measures three times over the course of a University semester. Longitudinal growth mixture analyses (GMA) revealed three distinct need satisfaction trajectories (Low-Decreasing, Moderate-Decreasing, and Moderate-Increasing). The Moderate-Increasing profile was associated with the highest levels of positive affect and effort. In contrast, the Low-Decreasing profile was associated with lower levels of positive affect, effort, and achievement, and higher levels of negative affect than the Moderate-Increasing profile.

1. Global need satisfaction

SDT proposes that the three psychological needs for autonomy, competence, and relatedness are essential nutriments for individuals' survival, growth, and integrity (Deci & Ryan, 2000), so that their satisfaction is seen as essential both for wellbeing and positive educational outcomes, an assertion that has been supported in a variety of studies and cultural contexts (e.g., Cordeiro et al., 2016; Sheldon & Filak, 2008). In contrast, when these needs are not satisfied, maladaptive outcomes (e.g., dropout intentions, burnout, psychological distress) are expected (e.g., Sulea, van Beek, Sarbescu, Virga, & Schaufeli, 2015; Taylor, Lekes, Gagnon, Kwan, & Koestner, 2012). These conclusions appear to hold irrespective whether researchers relied on a total score of need satisfaction encompassing the three psychological needs (e.g., Cheon, Reeve, & Song, 2016; Michou, Mouratidis, Ersoy, & Uğur, 2016), or on distinct measures of the needs for autonomy, competence, and relatedness (e.g., Johnston & Finney, 2010; Niemiec, Ryan, & Deci, 2009). The latter studies generally
identified relations between need satisfaction and the outcomes of a
similar magnitude across the three distinct measures of need satisfac-
tion. This observation suggests that, at least from an outcomes per-
spective, the global level to which students’ psychological needs are
satisfied appears to be at least as critical as the extent to which each
specific need is itself satisfied. This hypothesis is even consistent with
SDT, which underscores the fact that “psychological health requires
satisfaction of all three needs; one or two are not enough” (Deci & Ryan,
2000, p. 229).

Bifactor measurement models provide a way (e.g., Morin, Arens, &
Marsh, 2016; Reise, 2012) to directly assess this hypothesis, by relying
on an explicit partition of the covariance observed among need sa-
fatisfaction ratings into that explained by a global latent factor (the G-
factor: global need satisfaction) underlying responses to all indicators,
and a series of specific components (the S-factors: satisfaction of the
needs for autonomy, competence, and relatedness) exclusive to subsets
of indicators but not explained by the global component. As such, bi-
factor models allow researchers to simultaneously consider students'
global levels of need satisfaction, together with their specific needs for
autonomy, competence, and relatedness. Indeed, recent research evi-
dence has demonstrated that bifactor measurement models provide a
more accurate representation of the complex multidimensionality asso-
ciated with the measurement of psychological needs when compared
to more traditional exploratory or confirmatory factor analytic models
(Brunet, Gunnell, Teixeira, Sabiston, & Bélanger, 2016; Myers, Martin,
Ntoumanis, Celimi, & Bartholomew, 2014; Sánchez-Oliva et al., 2017;
Tóth-Király, Morin, Bóthe, Oroz, & Rigó, 2017). Interestingly, these
studies all reported the presence of a well-defined global need sa-
fatisfaction G-factor underlying responses to all ratings, whereas some of
them found that at least one of the S-factors retained only a negligible
amount of specificity once global levels of satisfaction were taken into
account (e.g., competence: Tóth-Király et al., 2017; autonomy: Sánchez-Oliva et al., 2017). Perhaps even more importantly, these
studies (e.g., Brunet et al., 2016; Sánchez-Oliva et al., 2017) also re-
ported that participants’ global levels of need satisfaction tended to be
the key component responsible for associations between need satisfac-
tion measures and a variety of covariates, underscoring the importance
of considering global levels of need satisfaction in future research on
the emergence, development, and consequences of need satisfaction.

2. Changes in psychological need satisfaction

The bulk of research on students' need satisfaction has relied on
cross-sectional designs, or short-term longitudinal designs precluding a
clear understanding of the developmental trajectories occurring at the
individual level (Ratelle & Duchesne, 2014). Longitudinal research is
necessary not only to achieve a better understanding of the longitudinal
stability and directionality of associations between variables, but also to
achieve a proper understanding of how need satisfaction evolves over
time for specific individuals (Grimm, Ram, & Estabrook, 2016). This
last advantage of longitudinal research appears critical in the context of
this study as SDT proposes need satisfaction to be partly situational in
nature (Vallerand, 1997). In other words, need satisfaction is seen as
emerging in part from the changing characteristics of the specific life
context to which a person is exposed rather than to be an inherently
stable individual characteristics. As such, the ability to study how need
satisfaction evolves over time for specific subgroup of individuals
would provide a rich window of opportunity into the various develop-
mental mechanisms at play in the emergence of relations between
need satisfaction and a variety of important developmental, educa-
tional, and professional outcomes. More precisely, the analytical ap-
proach (GMA) taken in the present study is specifically designed to
examine how the need satisfaction trajectories of distinct profiles of
University students evolve over the course of a semester, and to docu-
ment how these distinct trajectory profiles are related to various edu-
cational outcomes. For instance, this study will help to respond to
questions such as: Is a large proportion of University students char-
acterized by initially low levels of need satisfaction coupled with a
marked decreasing trajectory (Low-Decreasing profile)? What are the
educational outcomes associated with this need satisfaction trajectory?

Among the few exceptions to this lack of longitudinal research,
Wandel and Bundick (2011) conducted a 3-year longitudinal study of
414 University students. Relying on autoregressive cross lagged models,
these authors were mainly interested in obtaining a clearer picture of
the longitudinal rank-order stability in students’ levels of need sa-
fatisfaction, and the directionality of the longitudinal associations be-
tween hope and need satisfaction. Interestingly, their results supported
the idea that need satisfaction was mainly situational in nature and thus
only moderately stable over time (r = 0.33 to 0.49), and that hope was
only very minimally related to students’ levels of need satisfaction over
time. Marchand and Skinner (2007) reported a higher level of rank-
order stability among a sample of children followed up over a 7-month
period (r = 0.49 to 0.67), consistent with the ideas that children
(Grades 3 to 6) tend to be exposed to a more stable environment than
adults. Still, they also found significant relations between teachers' re-
port of their own motivational practices, and later levels of need sa-
fatisfaction among students, a result that has been replicated in a study
focusing on the impact of coaching on female adolescents gymnasts
measured twice seven months apart (Kipp & Weiss, 2015). In line with
these results, Cheon et al. (2016) demonstrated that a teacher-focused
intervention could result in a positive increase in middle and high
school students’ levels of need satisfaction over time, although esti-
mates of rank-order stability obtained across four waves of measure-
ment covering a school year remained of a similar magnitude (r = 0.55
to 0.69). Cox, Smith, and Williams (2008) obtained similar estimates of
stability (r = 0.44 to 0.68) with sixth- and seventh-grade students who
completed a survey containing a measure of need satisfaction on two
occasions, one year apart.

3. Need satisfaction trajectories

Despite their interest, these studies are limited in their focus on
rank-order stability in need satisfaction levels rather than on the esti-
mation of individual trajectories. In particular, rank-order stability does
not preclude the presence of normative increases or decreases in need sa-
fatisfaction over time, and the observed levels of rank-order stability
also remain low enough to suggest that substantial change still occurs
over time for a substantial proportion of the students. This suggests that
individual trajectories of need satisfaction may present substantial
inter-individual heterogeneity which has yet to be specifically con-
sidered in research. Part of this heterogeneity may be explained by the
presence of subpopulations characterized by different need satisfac-
tion trajectories over time, which may be particularly important to identify
for intervention purposes. It is noteworthy that previous studies all
relied on variable-centered analyses, which rest on the assumption that
all students are drawn from a single population following a similar
trajectory. These investigations were thus not designed to test for the
presence of developmental heterogeneity in psychological need sa-
fatisfaction and to verify the extent to which this heterogeneity was
related to the presence of unobserved subgroups of students following
qualitatively distinct trajectories. Person-centered analyses, such as
GMA, are specifically designed to explain longitudinal heterogeneity by
separating a general population into profiles of students presenting
qualitatively and quantitatively different trajectories (Muthén, 2002).
GMA thus represents an alternative to traditional variable-centered
analyses in addressing students’ changes in psychological need sa-
fatisfaction over time (Morin, Maiano, Marsh, Nagengast, & Janosz,
2013).

To our knowledge, a single study has so far relied on a person-
centered approach of students' need satisfaction trajectories (Ratelle &
Duchesne, 2014). In a study of 609 students followed annually from the
end of elementary school to the end of secondary school, Ratelle and
Duchesne (2014) relied on a restricted form of GMA to identify specific developmental trajectories of students’ need satisfaction over time and confirmed the presence of substantial developmental heterogeneity. More precisely, these authors revealed that the trajectories depicting how the satisfaction of students’ needs for competence, autonomy, and relatedness were each best represented according to five distinct profiles. Although each of these profiles presented differing levels of need satisfaction over time, they all tended to depict mostly stable trajectories, sometimes accompanied by slight increasing or decreasing tendencies with two noteworthy exceptions. These exceptions showed that 12% of the students reported a decrease in autonomy need satisfaction at the beginning of secondary school, whereas 6% of the students reported an increase in competence need satisfaction at the same moment. Ratelle and Duchesne (2014) further found that trajectory group membership was closely associated for the three needs, calling once again into question the true necessity of distinguishing among these three specific needs relative to a focus on global levels of need satisfaction. Perhaps even more importantly, they also demonstrated that all trajectory classes differed from one another in terms of academic, social, and emotional adjustment. This is important, since the only way to support a substantive interpretation of latent profiles is through a process of construct validation showing that these profiles present meaningful patterns of associations with theoretically significant covariates (Marsh, Lüdtke, Trautwein, & Morin, 2009; Morin, Morizot, Boudrias, & Madore, 2011).

4. The present study

4.1. Global need satisfaction trajectories

Unfortunately, despite the pioneering nature of their study, Ratelle and Duchesne (2014) relied on a restricted form of GMA in which it was assumed that all students would correspond exactly to the average longitudinal trajectory identified in their own profile (i.e., latent class growth analysis: Nagin, 1999). This highly restrictive assumption has been shown to result in the possible over-extraction of latent profiles of students following trajectories of a similar shape but different levels (Bauer & Curran, 2004; Muthén & Muthén, 2000), to result in drastically different results than more flexible methods allowing for the representation of within- and between-profile heterogeneity (Morin, Maïano et al., 2011), and, more generally, to lead to biased conclusions relative to most alternative GMA specifications (Diallo, Morin, & Lu, 2016). As such, it is perhaps not so surprising to note that many of the profiles identified by Ratelle and Duchesne (2014) presented roughly the same shape, and differed from one another mainly in terms of their global levels of need satisfaction over time.

To address this limitation, we rely on a more flexible GMA approach to investigate University students’ levels of global need satisfaction over the course of a semester. The decision to rely on a sample of University students is based on three distinct considerations. First, previously reviewed research suggests that need satisfaction levels may become less stable as students get older, thus possibly maximizing our ability to identify meaningfully distinct trajectory profiles. Second, SDT proposes that need satisfaction should be most relevant for self-determined activities (i.e., activities in which individuals engage out of pleasure and/or volition and choice; Vallerand, 1997). Given that University studies are more typically self-determined, relative to the mandatory nature of primary and secondary education, need satisfaction should thus be most relevant for the prediction of meaningful educational outcomes at this level of education. Finally, persistence in University studies is a critically important consideration for educational systems worldwide, as higher education is associated with multiple social, economic, and psychological consequences for the students themselves as well as the society as a whole (Voelkle & Sander, 2008). Among the key drivers of educational persistence and motivation, students’ level of psychological need satisfaction appears to represent a particularly important mechanism to consider (Jang et al., 2009). Yet, despite the importance of University education in terms of professional, social, and vocational achievement and success, need satisfaction has received relatively little attention in prior longitudinal research.

Although prior longitudinal studies suggest that need satisfaction trajectories should exhibit some stability, they also suggest that change is possible over the course of a few months, and more likely among this older age group (Cheon et al., 2016; Cox et al., 2008; Kipp & Weiss, 2015; Ratelle & Duchesne, 2014; Wandeler & Bundick, 2011). Due to the scarcity of research using a person-centered approach to identify need satisfaction trajectories in the educational domain, it is difficult to propose specific hypotheses about the nature and number of the expected trajectory profiles. Still, based on Ratelle and Duchesne (2014), we expect these trajectories to follow distinct longitudinal profiles, although the reliance on a less restrictive GMA approach suggest that fewer than five profiles might be required to fully depict University students’ need satisfaction trajectories. As such, we expect that between three and five profiles would be sufficient to adequately depict inter-individual heterogeneity in need satisfaction trajectories. Furthermore, to systematically test the assertion that need satisfaction is a mainly situational variable construct, we assess the extent to which these need satisfaction trajectory profiles depend on stable individual characteristics known to be relevant to the education area (i.e., sex, prior levels of achievement in college, grade repletion in college).

4.2. Outcomes of the need satisfaction trajectories

Following from Ratelle and Duchesne (2014), and based on the idea that it is critical to demonstrate the criterion-related validity of the extracted trajectory profiles in relation to meaningful external covariates (Marsh et al., 2009; Morin, Morizot et al., 2011), we also seek to contrast the extracted latent trajectory profiles in relations to students’ levels of positive and negative affect, effort, expected achievement level, and true achievement level at the end of the semester. These covariates were selected based on their documented importance in the educational area, their relevance to SDT, and results from prior research on students’ need satisfaction. Thus, we focus on the key educational outcomes of effort and positive affect given mounting research evidence supporting their important role in academic success (Gillet, Vallerand, Lafrenière, & Bureau, 2013; Trautwein & Lüdtke, 2007). We also consider negative affect, as this outcome is known to be a strong predictor of school dropout behavior (Fortin, Royer, Potvin, Marcotte, & Yergeau, 2004), which is in turn associated with numerous negative life outcomes in terms of employment and criminality (Bjerk, 2012).

Consistent with SDT predictions (Deci & Ryan, 2000), prior studies have generally supported the idea that higher levels of need satisfaction tended to be associated with more adaptive academic outcomes. More specifically, research evidence has shown that psychological need satisfaction is positively related to positive affect, and negatively linked to negative affect (Martela & Ryan, 2016; Martela, Ryan, & Steger, 2017; Vandercammen, Hofmans, & Theuns, 2014). In addition, research has also shown that need satisfaction has positive effects on students’ effort and achievement levels (Cerasoli, Nicklin, & Nassrelnagrawi, 2016; Taylor & Lonsdale, 2010). Ratelle and Duchesne (2014) also examined the effects of developmental trajectory membership on academic, social, and emotional adjustment at the end of high school. Overall, the best adjustment scores were observed for students with high levels of need satisfaction and an increasing trajectory, followed by those with moderate levels of need satisfaction, and finally those with low levels of need satisfaction. When we summarize all of the above, it seems that we can expect educational outcomes (i.e., positive and negative affect, effort, expected achievement, and observed achievement) to be differentially related to need satisfaction trajectory profiles. Specifically, we expect that profiles characterized by higher levels and/or by increasing levels of global need satisfaction would be associated with the most adaptive outcomes, whereas profiles characterized by lower and/or by
decreasing levels of global need satisfaction would be associated with the least desirable outcomes.

5. Method

5.1. Participants and procedure

The sample used in this study included a total of 461 first-year undergraduate psychology students (Mean age = 18.52; SD = 0.72), including 83 males and 378 females, enrolled in a French University. The educational context and undergraduate psychology curriculum to which students are exposed in this University are similar to those proposed in other French Universities, as well as to those implemented in most Western Universities. Specifically, the academic program presented in this University is based on an introduction to the field of psychology in general, as well as to its various subfields (clinical, developmental, educational, neuropsychological, etc.) and areas of applications (personality, behaviors, cognitions, etc.) and to quantitative research methods. As for the majority of French Universities, all the students who have a high-school diploma and want to apply for admission to this University can enroll in the undergraduate psychology program. The proportion of males and females, and age distribution of this sample is aligned with those of French undergraduate psychology students. Admission at the undergraduate level is not as restrictive in France as in other countries, and undergraduate studies are tuition-free, contributing to increase the representativeness of this sample. Participation was voluntary and all first-year students enrolled in the psychology program of this University were invited to complete a self-reported questionnaire two weeks after the beginning of the fall semester. Among these participants, 421 (91.3%) agreed to complete the questionnaire again at Time 2 (five weeks later) and 379 (82.2%) also completed the questionnaire at Time 3 (ten weeks after Time 1). At each data collection, we explained the general purpose of the study, participants provided informed consent, and then completed a 15 min questionnaire in class settings. Participants were ensured that their responses would be kept confidential and would not have any influence on their course grades. They were only required to provide a personal identification code to allow researchers to match their responses at each data collection point. All questionnaires were administered in French and instruments not already available in this language were adapted to French using a standardized back-translation procedure (Hambleton, 2005) by a panel of experts.

5.2. Measures

Need satisfaction. Participants’ need satisfaction was assessed with a questionnaire initially developed and validated by Gillet, Rosnet, and Vallerand (2008) (see also Gillet, Fouqueruea, Huyghebaert, & Colombat, 2016), which was slightly adapted to the educational context for purposes of the present study. This questionnaire includes 9 items scored using a 7-point Likert-type scale ranging from 1 (strongly disagree) to 7 (strongly agree). It assesses three dimensions (3 items each) of students’ psychological need satisfaction, including autonomy (e.g., “Generally, I feel free to express my ideas and opinions”; Time 1 $\alpha = 0.55$; Time 2 $\alpha = 0.65$; Time 3 $\alpha = 0.78$), competence (e.g., “Often, I feel that I am very efficient”; Time 1 $\alpha = 0.72$; Time 2 $\alpha = 0.81$; Time 3 $\alpha = 0.81$), and relatedness (e.g., “I have a lot of sympathy for the persons with whom I interact”; Time 1 $\alpha = 0.67$; Time 2 $\alpha = 0.75$; Time 3 $\alpha = 0.76$). As in previous research (Michou et al., 2016), we rely in the present study on a score of global need satisfaction (Time 1 $\alpha = 0.75$; Time 2 $\alpha = 0.82$; Time 3 $\alpha = 0.83$).

Positive and negative affect. Participants’ levels of positive (3 items; i.e., “active”, “determined”, and “enthusiastic”; Time 1 $\alpha = 0.72$; Time 2 $\alpha = 0.80$; Time 3 $\alpha = 0.79$) and negative (3 items; i.e., “afraid”, “nervous”, and “scared”; Time 1 $\alpha = 0.66$; Time 2 $\alpha = 0.75$; Time 3 $\alpha = 0.79$) affect in their studies were assessed with the two relevant subscales from the Short Form of the Positive and Negative Affect Schedule (Thompson, 2007; Watson, Clark, & Tellegen, 1988). Responses were made on a 5-point Likert-type scale (1-not at all to 5-very much).

Effort. Participants’ level of effort was assessed using five items (e.g., “I put a lot of effort in my classes”; Time 1 $\alpha = 0.87$; Time 2 $\alpha = 0.89$; Time 3 $\alpha = 0.90$) from the effort/importance subscale of the Intrinsic Motivation Inventory (McAuley, Duncan, & Tammen, 1989). Responses were given on 1 (strongly disagree) to 7 (strongly agree) Likert-type scale.

Expected achievement. At each time point, participants’ were asked to report their expected grades (between 0 and 20) at the end of the fall semester on a 0 to 20 scale corresponding to the way class grades were provided in this University.

Observed achievement. At the end of the semester, grade transcripts were received from the administrative office of the University. The French grading system uses grades varying between 0 and 20 for each course.

6. Analyses

6.1. Model estimation and missing data

All models estimated in the present study were estimated using Mplus 7.4 (Muthén & Muthén, 2015) using the robust Maximum Likelihood (MLR) estimator, which provides parameter estimates, standard errors, and goodness-of-fit indices that are robust to the non-normality of the response scales used in the present study. These models were estimated in conjunction with Full Information Maximum Likelihood (FIML; Enders, 2010) procedures to account for the relatively limited amount of missing responses present at the item level for participants who completed each specific time point (0%-2.5%). FIML also allowed us to estimate all longitudinal models using the data from all respondents who completed at least one wave of data rather than using a listwise deletion strategy focusing only on those having answered all, or a subset, of the time waves (Enders, 2010; Graham, 2009). In total, 461 students provided a total of 1237 time-specific ratings (M = 2.68 time-specific ratings per student), with 345 (74.8%) students completing all three time-points, 86 (18.7%) completing 2 time-points, and 30 (6.5%) completing a single time-point. FIML has comparable efficacy to multiple imputation, while being more efficient (Enders, 2010; Graham, 2009; Jeličić, Phelps, & Lerner, 2009; Larsen, 2011).

6.2. Preliminary analyses

Rather than using scale scores (the mean or sum of the items) to estimate the trajectories and their relations with predictors and outcomes, factor scores (estimated in standardized units with $M = 0$, $SD = 1$) from preliminary measurement models were used as inputs for the analyses. The measurement models for the need satisfaction variables were estimated using bifactor confirmatory factor analyses (Holzinger & Swineford, 1937; Reise, 2012). This decision is based on recent evidence showing that bifactor measurement models are naturally suited to the representation of need satisfaction (Sánchez-Oliva et al., 2017) based on SDT (Deci & Ryan, 2000). Sánchez-Oliva et al. (2017) showed that a bifactor representation provided a way to obtain a direct and precise estimate of the global level of need satisfaction presented by participants across all three specific needs, which is used in this study to estimate participants’ growth trajectories. To ensure comparability in the measures across time waves, these factors scores were saved from longitudinally invariant measurement models (Millsap, 2011). Although factor scores do not explicitly control for measurement errors the way latent variables do, they do provide a partial control for measurement errors (Skonidal & Laake, 2001) by giving more weight to more reliable items (i.e., items characterized by higher factor loadings and lower uniquenesses). Furthermore, factors

Note. *p < 0.05; **p < 0.01; T1: Time 1; T2: Time 2; T3: Time 3; for need satisfaction, positive and negative affect, and effort, scores are factor scores from preliminary models.
scores are able to preserve the nature of the underlying measurement structure (e.g., invariance) better than scale scores (for additional discussions of factor scores, see Morin, Boudrias, Marsh, Madore, & Desrumaux, 2016; Morin, Meyer, Creusier, & Biétry, 2016). Details on these measurement models and their longitudinal invariance are reported in the online supplements. The correlations between all variables used in the main analyses (i.e., the factor scores saved from these final measurement models and single item measures) are reported in Table 1.

6.3. Growth mixture analyses (GMA)

In this study, linear GMA models2 with one to eight latent trajectories of global need satisfaction were estimated and compared. GMA are built from latent curve models (Bollen & Curran, 2006), and aim to identify subgroups of participants following distinct longitudinal trajectories (Grimm et al., 2016; Morin, Maïano et al., 2011). Linear GMA summarize a series of repeated measures by the estimation of random intercepts and slope factors reflecting, respectively, the initial level of the growth trajectories and the rate of change over time. In the present study, time codes on the slope factors were set to 0 at Time 1 (to allow the intercept factors to reflect global need satisfaction levels at the initial time point), 1 at Time 2, and 2 at Time 3 to reflect the presence of three equally spaced measurement points. To avoid converging on a local maxima, all of these models were estimated using 10,000 random sets of start values, 1000 iterations, and 500 solutions for final stage optimization (Hipp & Bauer, 2006). A more technical presentation of GMA is provided in the online supplements.

Current recommendations from the statistical literature are that GMA should, whenever possible, be estimated while allowing all models parameters (intercept and slope means, intercept and slope variances and covariances, and time-specific residuals) to be freely estimated in all profiles (Diallo et al., 2016; Morin, Maïano et al., 2011). However, this recommendation comes with the recognition that this free estimation of all model parameters is not always possible due to the tendency of these more complex models to converge on improper solutions, or not to converge at all (Diallo et al., 2016), which is typically taken to reflect overparameterization and the need to rely on simpler models (Chen, Bollen, Paxton, Curran, & Kirby, 2001). This was the case in the present study. In such situations, the recommendation is to implement equality constraints across profiles on model parameters to achieve a more parsimonious representation (Diallo et al., 2016). Here, we relied on the Mplus default parameterization which sets the latent variance-covariance matrix to be invariant across latent profiles. We also allowed the time-specific residuals to be freely estimated in each classes, but homoscedastic across time points (Enders & Tofghi, 2008; Li & Hser, 2011). This specification of the residuals is consistent with a multilevel operationalization of growth models, and results in GMA which are assumed to provide an equally efficient representation of the all repeated measures, while allowing this explanatory power to differ across latent profiles.

Controls. Tests aiming to determine whether demographic control variables needed to be retained for the subsequent analyses were conducted.

Outcomes of Profile Membership. Time-varying outcomes levels measured at each time point (positive affect, negative affect, effort, expected achievement, and observed achievement) were contrasted across profiles using a model-based approach proposed by Lanza, Tan, and Bray (2013) and implemented through the Auxiliary (DCON) function (Asparouhov & Muthén, 2014).

---

2 The decision to rely on linear models is based on the initial comparison of linear versus multibase latent curve models, which revealed no evidence of non-linearity. Multibase models provide a way to test for the presence of non-linearity in models including three time points through the free estimation of the second loading on the slope factor (i.e., time code). In addition, Metha and West (2000) showed that relying on uniform time codes when participants differ in age is proper when: (1) the regression of the intercept of a latent curve model on age is equal to the slope, and (2) the regression of the slope on age is equal to zero. In this study, participants are close in age, of the same grade level, and results supported both conditions, as shown by non-significant $\chi^2$ difference tests (condition 1: $\Delta\chi^2 = 0.101$, df = 1; Condition 2: $\Delta\chi^2 = 0.000$, df = 1; Conditions 1 and 2: $\Delta\chi^2 = 0.122$, df = 2).

7. Results

7.1. Unconditional models

The results from the estimation of the alternative GMA solutions converged on a three-profile solution. The rationale supporting this solution is reported in the online supplements. This solution is graphically presented in Fig. 1, and specific parameter estimates are reported in Table S5 of the online supplements. It is important to keep in mind that these trajectories were estimated on the basis of invariant factor scores with a mean of 0 and a standard deviation of 1 obtained on the global need satisfaction factor in the context of preliminary analyses reported in the online supplements. This means that 0 corresponds to the average level of global need satisfaction, and that deviations from this mean are expressed in standard deviation units.

In comparing the profiles, it is first informative to note that Profiles 1 and 2 are characterized by an initial level (i.e., the mean on the intercept factor) that are slightly higher than average by about 0.2 SD, and virtually identical. However, clear differentiations occur between these two profiles as the semester evolves leading to a difference of about 0.50 SD in global need satisfaction levels at the end of the semester. Profile 1 characterizes 11.50% of students with initially moderate levels of global need satisfaction, which are characterized by a slight decreasing tendency over time (corresponding to −0.103 SD units per time point). In contrast, Profile 2 characterizes 61.39% of the students presenting initially moderate levels of global need satisfaction, which are characterized by a slight increasing tendency over time (0.106 SD units per time point). Finally, Profile 3 is the most concerning, and characterizes 27.11% of students presenting an initially low levels of global need satisfaction coupled with a marked decreasing trajectory (−0.305 SD units per year).

Statistics regarding the classification accuracy of the students into their most likely profile are reported in Table S6 of the online supplements, and indicate a relatively high level of classification accuracy for members of all three profiles, ranging from 80.2% for the Low-Decreasing profile (3), to 87.8% for members of the Moderate-Decreasing profile (1), and to 90.4% for members of the Moderate-Increasing profile (2), consistent with a relatively high entropy value (0.717).3

7.2. Controls

Once the optimal number of profiles has been selected, we conducted a series of tests aiming to determine whether demographic controls assessed at Time 1 (sex, prior level of achievement, grade repetition) needed to be retained for subsequent analyses as time-invariant predictors (TIP). These controlled variables were included using the start values from the final retained unconditional GMA model (Diello, Morin, & Lu, 2017; Morin, Meyer et al., 2016) and a series of alternative models were contrasted, following recommendations from Diallo et al. (2017) and previously implemented in applied research by Morin and colleagues (Morin, Maïano et al., 2011, 2013; Morin, Rodríguez, Falgu, Maïano, & Janosz, 2012). First, a null effects model was estimated in which the effects of the controls on the probability of membership in all profiles, as well as on the growth factors, were constrained to be zero. Second, a first alternative model was estimated in which the controls were allowed to predict profile membership through a multinomial logistic regression. Tests were then conducted on additional models in which controls were also allowed to influence within-profile variation in the intercepts and slopes of the trajectories (via a multiple regression equation), and in which these effects were allowed to vary from one profile to another. Results from models incorporating controls are reported in the bottom section of Table S4 and support the null effects model. Examination of the detailed parameters estimates from these alternative models supports this conclusion regarding the lack of meaningful associations between the controls and the profiles, and the decision to exclude controls from further analyses.

7.3. Time-varying outcomes

Results from the comparison of the time-specific outcomes across profiles are reported in Table 2. These results reveal that the three profiles are very clearly differentiated on the outcomes considered, and that the pattern of associations between profiles and outcomes differs across outcome. Levels of negative affect are indistinguishable between the Moderate-Decreasing and Moderate-Increasing profiles, although both of these profiles present lower levels of negative affect than the Low-Decreasing profile. However, levels of positive affect are highest among the Moderate-Increasing profile, followed by the Moderate-Decreasing profile, and finally by the Low-Decreasing profile, with all pairwise comparisons being significant. Furthermore, levels of effort are indistinguishable between the Moderate-Decreasing and Low-Decreasing profiles, although both of these profiles present lower levels of effort.
than the Moderate-Increasing profile. Finally, it is interesting to note that expected achievement levels generally follow the same pattern of differences than observed achievement at the end of the semester, at least at the first and last time points where these outcomes are lower among the Low-Decreasing profile than among the other two profiles. It is however interesting to note that in the middle of the semester, students corresponding to the Moderate-Decreasing profile also report higher expected achievement levels than members of the Low-Decreasing profile.

With the sole exception of the aforementioned difference in expected achievement levels observed in the middle of the semester, most of these differences are stable over time. Taken together, these results suggest that, when compared to the other profiles, members of the Moderate-Increasing profile present higher levels of positive affect and invest more effort in their studies. In comparison to this Moderate-Increasing profile, members of the Low-Decreasing profile display less positive affect and more negative affect, invest less effort in their studies and, possibly as a result of these lower effort levels, present lower levels of achievement. Finally, members of the Moderate-Decreasing profile also present lower levels of positive affect and invest less effort in their studies, but display comparable levels of negative affect and achievement as members of the Moderate-Increasing profile.

8. Discussion

Prior studies have shown that the satisfaction of the three psychological needs for autonomy, competence, and relatedness tended to be associated with more positive academic outcomes (e.g. Cordeiro et al., 2016; Wang et al., 2017). However, in the educational area, prior research has largely ignored individual developmental trajectories (Ratele & Duchesne, 2014). To better understand how need satisfaction evolves over time for specific subgroups of students, the present study was designed to inform how the need satisfaction trajectories of distinct profiles of University students evolved over the course of a semester and related to various educational outcomes (i.e., positive and negative affect, effort, expected achievement, and objective achievement).

8.1. Need satisfaction trajectories

Recently, Ratelle and Duchesne (2014) identified longitudinal trajectories of students’ need satisfaction and confirmed the presence of substantial developmental heterogeneity (five distinct profiles for each specific need). However, they relied on a restricted form of GMA (i.e., latent class growth analysis) in which it was assumed that all students would correspond exactly to the average longitudinal trajectory identified in their own profile, and treated each need separately without considering evolution in students’ global levels of need satisfaction. In the present study, we relied on a more flexible GMA approach and identified three distinct profiles of students’ global need satisfaction: (1) Students with initially moderate levels of global need satisfaction, which are characterized by a slight decreasing tendency (Moderate-Decreasing profile); (2) students with initially moderate levels of global need satisfaction, which are characterized by a slight increasing tendency (Moderate-Increasing profile); and (3) students with initially low levels of global need satisfaction coupled with a marked decreasing trajectory (Low-Decreasing profile). Students’ need satisfaction thus fluctuated in a heterogeneous fashion over the course of a University semester. Interestingly, our results also supported the idea that need satisfaction is at least partly situational in nature and thus fluctuates over time (Cheon et al., 2016; Cox et al., 2008; Marchand & Skinner, 2007).

These findings are the first to document longitudinal trajectories of University students’ global need satisfaction over the course of a semester. Our participants were first-year undergraduate psychology students who have recently undergone the transition from high school to University, with the accompanying changes in teachers and learning structure, as well as classroom composition that changes over class. Some might even experience more than one simultaneous life transition when, for instance, they had to move to another neighborhood or city to enter University. More generally, the freshman year is known to represent a challenging life transition accompanied by major changes in students’ educational and social environments, incorporating new and unfamiliar academic tasks and learning situations, and evolving social networks (DeClercq, Galand, & Frenay, 2017; Perry, Hladkyj, Pekrun, & Pelletier, 2001). These changes might influence students’ psychological need satisfaction trajectories and explain why groups of students reported changing need satisfaction trajectories over the course of their first University semester. As such, the specific context of the freshman year might have generated slightly more elevated levels of instability in need satisfaction trajectories than what would be observed across more stable life contexts.

Future longitudinal research would be needed to more clearly address this possibility, and to better document the time-invariant (personal characteristics) and time-varying (associated with the academic and social life contexts) characteristics that predict membership into these various trajectory profiles. Interestingly, our results showed that these trajectory profiles were independent from students’ demographic characteristics (sex, prior level of achievement, grade repetition), suggesting that changing life contexts might be particularly relevant to consider. For instance, in line with recent studies (Taylor & Lonsdale, 2010) showing that teachers’ behaviors relate to students’ levels of need satisfaction, these additional investigations might look at the impact of University teachers’ autonomy-supportive and controlling behaviors. Similarly, following from studies supporting the key role of the social context in supporting students’ need satisfaction in the academic area (Lu, Walsh, White, & Shield, 2017), it might be interesting to look at the role of changes in students’ lives circumstances (moving away from family, integrating new peer groups, etc.) in predicting profile membership.

8.2. Outcomes of the need satisfaction trajectories

Still, our findings clearly support the practical importance of the identified need satisfaction trajectories in the prediction of academic outcomes, showing well-differentiated associations between profile membership and the various outcomes considered in this study. First, the Moderate-Increasing profile was associated with the highest levels of positive affect and effort. Second, members of the Low-Decreasing profile tended to display less positive affect and more negative affect, invest less effort in their studies, and present lower levels of achievement than those from the Moderate-Increasing profile. Finally, the Moderate-Decreasing profile was associated with lower levels of positive affect and effort than the Moderate-Increasing profile, while these two profiles could not be distinguished from one another on negative affect and achievement. These results support SDT’s propositions (Deci & Ryan, 2000) in demonstrating the positive effects of global levels of need satisfaction. They are also well aligned with those from prior studies conducted in the educational area showing that higher levels of global or specific need satisfaction were particularly beneficial in terms of social, academic, and personal–emotional adjustment (Jang et al., 2009; Ratelle & Duchesne, 2014).

It was interesting to note that the Moderate-Increasing profile tended to be associated with more positive outcomes, at least in terms of positive affect and effort, than the Moderate-Decreasing one. Furthermore, our findings demonstrate that students with comparable initial levels of need satisfaction ended up displaying similar levels of negative affect and achievement irrespective of whether their degree of satisfaction increased or decreased over the course of the semester. Future studies would be needed to verify the possibility that the negative effects of decreases in need satisfaction in terms of achievement and negative affect can be temporally lagged and only emerge in the following semester. Clearly, the adoption of a longer term longitudinal perspective
might have revealed relations occurring at a more fundamental trait level. Conversely, these alternative time frames might have hidden the currently observed relations. Ultimately, longitudinal evidence remains stronger in terms of clarifying the directionality of associations than cross-sectional research, but needs to be built incrementally from an accumulation of studies exploring alternative time frames. Finally, due to limitations posed by the sample size, the current study solely focused on students’ trajectories of global need satisfaction, without simultaneously considering their more specific trajectories of competence, relatedness, and autonomy need satisfaction. Despite recent evidence providing tentative support to the key role played by global need satisfaction (Brunet et al., 2016; Sánchez-Oliva et al., 2017), it remains critical for future studies to more closely consider students more specific need satisfaction trajectories (e.g., Ratelle & Duchesne, 2014) and how they related to key developmental and educational outcomes.

8.4. Practical implications

From a practical perspective, our findings suggest that teachers should be particularly attentive to students displaying low and decreasing levels of global need satisfaction (Low-Decreasing profile) as these appear to be at risk for a variety of educational difficulties. Such a trajectory might be identified by using a short version of a scale assessing psychological need satisfaction at the beginning of each semester for example, which could be presented as a request for feedback from the teacher. This way, teachers could easily become aware of students, or groups of students, displaying low levels of need satisfaction and attempt to intervene before the emergence of undesirable outcomes. For example, teacher-focused interventions and support systems might be made available for teachers in order to help them increase students’ levels of need satisfaction over time (Cheon et al., 2016). In the existing literature, numerous studies have shown that autonomy-supportive teaching behaviors were positively related to psychological need satisfaction (Jang et al., 2009; Sheldon & Filak, 2008). Thus, having teachers displaying higher levels of autonomy-supportive behaviors could be associated with a greater likelihood of membership into the most desirable profile (Moderate-Increasing). Incorporating autonomy-supportive structure into classes may thus be an important pedagogical consideration. Jang, Reeve, and Halusic (2016) recently tested the educational utility of “teaching in students’ preferred ways” as a new autonomy-supportive teaching strategy. Results revealed that students who received a preferred way of teaching (i.e., teachers take their students’ perspective and adjust how they deliver a lesson plan so that it aligns with students’ preferred ways of teaching) perceived their teacher as more autonomy-supportive and had more positive outcomes. Thus, “teaching in students’ preferred ways” represents a way of teaching that may increase students’ psychological need satisfaction.
