Abstract

Aim: To examine whether supportive supervisor (transformational leadership) and coworker (autonomy-supportive) behaviours predict occupational commitment and turnover intention over time through autonomous motivation.

Background: Nurse turnover is a serious issue in several countries, straining the efficiency of the healthcare system and compromising both the quality and accessibility of healthcare.

Method: Longitudinal data were collected over 12 months from 387 French-Canadian registered nurses. Structural equation modeling was used to test the hypothesized model.

Results: The relationships between predictors at Time 1 (supervisor and coworker behaviours) and occupational commitment and turnover intention at Time 2 are mediated by autonomous motivation at Time 1.

Conclusion: In times of global scarcity, the present findings provide insights into how the healthcare work environment acts on nurses' occupational turnover and commitment.

Implications for Nursing Management: Healthcare organizations are advised to foster supportive work environments and promote autonomous motivation to sustain the nursing workforce.

KEYWORDS

autonomous motivation, autonomy support, nurse turnover and retention, occupational commitment, transformational leadership

1 | INTRODUCTION

Although research has suggested for some time that nurse turnover is a serious concern in several countries (Perreira et al., 2018), most empirical studies have focused on interrole transitions, such as

organizational commitment, with less attention directed towards occupational turnover indicators including affective commitment and intention to leave the profession (Van der Heijden et al., 2018). Yet, if staff turnover incurs significant direct costs (e.g., recruiting, replacement) as well as indirect costs (e.g., loss of productivity) for healthcare

organizations, quitting the profession substantially adds to this burden, further straining the efficiency of the healthcare system and compromising both access to and quality of care and services (Hayes et al., 2012). This situation is all the more alarming given the global shortage of nurses and midwives which is estimated to reach 9 million by 2030 (World Health Organization, 2020).

Several psychosocial factors have been associated with nurses' retention in the occupation. These factors generally fall into two categories, namely, (1) work environment (e.g., supervisor and coworker support, job overload and lack of professional autonomy) and (2) individual (e.g., job attitudes, demographic characteristics such as age and job experience) factors (e.g., Pursio et al., 2021; Van der Heijden et al., 2018). However, among the individual factors assessed, the role of autonomous motivation at work has not been clearly established. Yet, recent work (e.g., Fernet et al., 2020) suggests that nurses who emotionally disengage from their occupation previously experience a gradual decline in autonomous motivation, defined by self-determination theory (SDT; Ryan & Deci, 2017) as the sense of being able to act according to their own choices, values and interests. Despite this finding, research is currently limited as to the temporal relationship between nurses' autonomous motivation and occupational commitment and turnover intention. It remains unclear whether, and how, social work environment factors may contribute to nurses' occupational commitment and turnover intention over time. Turnover intention refers to a deliberate and conscious willingness to quit the occupation or the organization (Tett & Meyer, 1993). As for commitment, it reflects nurses' emotional attachment, involvement and identification with the occupation (Meyer et al., 1993). In addition to being associated with significant organizational and societal costs (Daouda et al., 2021; Hayes et al., 2012), these two variables are associated with actual turnover (Van der Heijden et al., 2018).

To address this issue, we tested a model which posits that nurses' perceptions of supportive behaviour from their immediate supervisor and coworkers relate to their autonomous motivation at work, which simultaneously predicts greater affective commitment to the occupation and lower intention to leave it over time. This study offers three main research contributions. First, we address the need for research to improve our understanding of why nurses intend to leave the occupation (Baljoon et al., 2019). To date, research has primarily focused on motivational correlates (e.g., job satisfaction), rather than examining the underlying reasons for being fully engaged in the job (Fernet et al., 2017). The present longitudinal study allows us to address this gap by examining the temporal relationship between autonomous motivation and two well-established occupational turnover indicators (commitment and turnover intention). As the occupational turnover literature is largely based on cross-sectional evidence, we aimed to offer a more comprehensive understanding of the dynamic nature of nurses' autonomous motivation. Despite the relatively stable nature of occupational commitment and turnover intention (Fernet et al., 2020), this would suggest that autonomous motivation can produce a motivational drive that stimulates nurses to become more committed and less inclined to leave the profession over time. Second, we assess the contribution of the perceived behaviours of two key

agents of the organization (i.e., immediate supervisor and coworkers) in the prediction of nurses' motivation. By drawing attention to the complementary and relative role of these agents' behaviours on work motivation (Jungert et al., 2021), this research suggests different avenues for intervention with nurses. Third, this study allows us to better understand the psychological mechanisms involved in occupational commitment and turnover intention. By proposing autonomous motivation as an explanatory mechanism, we advance research by identifying psychological pathways by which the prevailing social context in health care organizations is liable to act on nurses' occupational turnover over time.

2 | THEORETICAL BACKGROUND

2.1 | Autonomous motivation

SDT (Ryan & Deci, 2017) provides a useful framework for understanding nurses' motivation. Focusing on both the quantitative and qualitative aspects of motivation, SDT distinguishes two main forms of motivation: Autonomous and controlled. In autonomous motivation, an effort is made for the pleasure and satisfaction of performing the task (intrinsic motivation) or because it allows for the attainment of objectives aligned with one's personal values (identified regulation). In contrast, controlled motivation refers to efforts made in response to internal (introjected regulation; avoiding anxiety or guilt or achieving a sense of self-worth) or external (external regulation; avoiding constraints or obtaining material or social rewards) pressures. In the present study, we focus on autonomous motivation, as it is more sensitive than controlled motivation to work environment factors (Fernet et al., 2015) and is a better predictor of change in attitudes at work (e.g., commitment, turnover intention; Austin et al., 2020).

2.2 | Social work environment predictors of autonomous motivation

According to SDT, employee motivation is largely influenced by environmental conditions in the workplace including the interpersonal work climate (Gagné & Deci, 2005). An environment that provides conditions supporting employees' growth and development contributes to their autonomous motivation (Ryan & Deci, 2017). Research has shown that supportive behaviours, both from the immediate supervisor and coworkers in the form of leadership or autonomy support, can facilitate employees' autonomous motivation (Jungert et al., 2021).

2.2.1 | Supportive supervisor behaviours

Transformational leadership theory (Bass, 1985) arguably provides one of the best-established conceptualizations of supportive supervisor behaviours in the nursing context (Cummings et al., 2018). This

framework is based on four types of behaviour: Idealized influence (serving as role model), inspirational motivation (inspiring others to become fully committed to organizational goals), intellectual stimulation (encouraging others to be creative and innovative) and individualized consideration (providing a supportive climate, paying attention to each nurse's needs). Several studies support the effect of an immediate supervisor's transformational leadership behaviours on nurses' autonomous motivation (e.g., Fernet et al., 2015). These behaviours promote autonomous motivation as they create the conditions required for the satisfaction of basic psychological needs (Ryan & Deci, 2017) and for the appropriation of work resources conducive to performance (e.g., Fernet et al., 2015). The theory and available findings lead us to propose the following hypothesis:

Hypothesis 1. Supportive supervisor behaviours at Time 1 are positively associated with nurses' autonomous motivation at Time 1.

2.2.2 | Supportive coworker behaviours

Although research in the nursing context has focused more on the leadership behaviours of the immediate supervisors, the behaviours of coworkers likely play an important role in motivating nurses (e.g., Jungert et al., 2021) for two main reasons. First, the reality of many healthcare organizations, particularly in a context of a shortage, leads them to orient their management strategies towards the achievement of specific results, such as accessibility and quality of services, thus promoting task-focused leadership (Cummings et al., 2018). This approach leaves immediate supervisors with fewer opportunities and time to support, coach and motivate their team members (Shao et al., 2019). Second, the departments and units in which nurses operate generally rely on small teams to perform well, which makes collaboration and supportive behaviours essential for motivation and commitment (Galletta et al., 2019).

According to SDT (Ryan & Deci, 2017), supportive coworker behaviours foster autonomous motivation by creating an environment conducive to communication, information sharing and recognition. A nurse can help another by giving constructive comments that allow, for example, the colleague to grasp the meaningful rationale or the merits of a task (Reeve & Cheon, 2016). A nurse can also respect a colleague's perspective, by being available to give information, clarify any ambiguities related to the position or task, answer questions and offer guidance (Fernet et al., 2015). Jungert et al. (2021) have shown that such coworkers' autonomy-supportive behaviours enhance autonomous motivation (i.e. intrinsic motivation) of employees in a social occupational context. Although few studies have examined the relationship between autonomy-supportive behaviours from coworkers and nurses' autonomous motivation, the simultaneous consideration of supportive behaviours of the immediate supervisor and coworkers will provide insight into their relative contribution. We thus propose the following hypothesis:

Hypothesis 2. Supportive coworker behaviours at Time 1 are positively associated with nurses' autonomous motivation at Time 1.

2.3 | Autonomous motivation and occupational commitment and turnover intention

Growing empirical evidence suggests that autonomous motivation at work promotes employee adaptation and functioning (Ryan & Deci, 2017). In the nursing context, nurses' autonomous motivation has been correlated with a variety of job attitudes related to retention, including occupational commitment, and negatively correlated with the intention to leave the organization and the nursing profession (Fernet et al., 2017; Fernet et al., 2020; Galletta et al., 2019). However, as past research has mainly utilized cross-sectional designs, little is currently known about the temporal relationship between motivation and occupational commitment and turnover intention.

2.3.1 | Occupational affective commitment

Occupational affective commitment is a unique construct that captures the psychological relationship that nurses develop with their occupation (Van der Heijden et al., 2018). The emotional attachment that nurses experience towards their profession allows them to maintain positive feelings towards their position and sustains their occupational commitment (Meyer et al., 1993). According to SDT, this level of emotional attachment is expected to depend on the reasons that led the nurses to invest in their occupation. When nurses' efforts are fully aligned with their choices and values (i.e., high autonomous motivation), this should strengthen their emotional attachment and commitment to their role. We thus propose the following hypothesis:

Hypothesis 3. Nurses' autonomous motivation at Time 1 positively predicts occupational affective commitment at Time 2.

2.3.2 | Occupational turnover intention

As the intent to leave refers to the conscious and deliberate desire to quit the profession (Tett & Meyer, 1993), it could stem from underlying reasons which motivate nurses to invest effort into their work (Fernet et al., 2017). Whereas autonomous motivation is characterized by volition and self-endorsement of choices and actions, nurses who do not find pleasure, satisfaction, or a genuine interest in performing tasks aligned with their personal values could be inclined to leave their occupation. According to Sheldon and Elliot (1999), the self-consistent nature of autonomously motivated activities is likely to create a sense of genuineness, which should allow autonomously motivated nurses to feel alive and authentic. Because they appreciate having the opportunity to express their true selves, autonomously motivated nurses

would be more inclined to remain in the profession. Accordingly, we propose the following hypothesis:

Hypothesis 4. Autonomous motivation at Time 1 negatively predicts occupational turnover intention at Time 2.

2.4 | The mediating role of autonomous motivation

Implicit to all four hypotheses and in SDT (Ryan & Deci, 2017) is the notion that supportive behaviours have an effect on occupational commitment and turnover intention through autonomous motivation. Despite the lack of empirical evidence in a nursing context, results from several organizational studies support this motivational sequence (see Ryan & Deci, 2017). Thus, we explicitly predict a mediated model.

Hypothesis 5. Autonomous motivation at Time 1 mediates the relationships between perceived supportive supervisor and coworker behaviours at Time 1 and occupational commitment and turnover intention at Time 2.

3 | METHOD

3.1 | Study design and sample

The participants of this 12-month longitudinal study were French-Canadian registered nurses working in the public healthcare sector. Our sample was drawn from a random mailing list of 665 nurses, members of the Quebec Nursing Association who agreed to be contacted for academic research purposes. Eligibility criteria was limited to the ability to read and understand French. All participants were asked to provide informed consent, before completing each online questionnaire. They were informed about the objectives of the research, told that participation was voluntary and confidential and

notified that they could freely withdraw from the project at any time. Approval for this study was obtained from the Ethic Committee of the principal researcher's institution. Out of this list, 387 nurses took part in our survey either at T1 (May 2014; $n = 302$) or T2 (May 2015; $n = 206$) and represented the final sample (overall response rate: 58%). Most participants were women (88.9%; $n = 344$) and held a permanent position (78.2%; $n = 280$) and 54.9% ($n = 196$) worked full time. The mean sample age was 29.15 years ($SD = 9.25$) and average length of experience in nursing was 4.19 years ($SD = 9.41$).

3.2 | Measures

All variables were administered in French at both time points with the exception of the predictors (supportive supervisor and coworker behaviours), which were assessed at Time 1 only (means, standard deviations, latent correlations are presented in Table 1). Validity and reliability of the French-Canadian version of these measures have been supported in prior studies (Fernet et al., 2017; Fernet et al., 2020). For all variables, higher scores reflect greater levels of each corresponding construct.

3.2.1 | Supportive supervisor behaviours

The seven-item Global Transformational Leadership scale (GTL; Carless et al., 2000) was used to assess nurses' perceptions of supportive leadership behaviours of their immediate supervisor ($\alpha = .94$; "He/she fosters trust, involvement and cooperation among team members"). Items were scored on a five-point scale ranging from "never" to "almost always".

3.2.2 | Supportive coworker behaviours

A three-item adapted version of Blais et al.'s (1991) scale was used to assess autonomy-supportive behaviours from coworkers ($\alpha = .75$). Participants were asked to rate on a seven-point scale from "do not agree at all" to "very strongly agree" the extent to which their

TABLE 1 Latent correlations between the variables

1. Autonomous motivation (T1)	—							
2. Occupational commitment (T1)	.588	—						
3. Occupational turnover intention (T1)	-.330	-.733	—					
4. Supportive supervisor behaviours (T1)	.346	.279	-.202	—				
5. Supportive coworker behaviours (T1)	.571	.418	-.366	.352	—			
6. Autonomous motivation (T2)	.778	.511	-.438	.269	.540	—		
7. Occupational commitment (T2)	.647	.944	-.729	.340	.471	.682	—	
8. Occupational turnover intention (T2)	-.392	-.590	.684	-.224	-.439	-.511	-.667	—

Note. All associations are significant at $p < .001$.

colleagues interacted with them in a given way (e.g., “My colleagues provide me with constructive feedback regarding my work and help me improve it”).

3.2.3 | Autonomous motivation

Two dimensions of the Revised Motivation at Work Scale (R-MAWS; Gagné et al., 2015) were used to assess autonomous motivation (T1 $\alpha = .82$; T2 $\alpha = .87$): Intrinsic motivation (three items; e.g., “Because my work is stimulating”) and identified regulation (three items; e.g., “Because this job has a personal significance for me”). Respondents scored on a seven-point scale from “not at all for this reason” to “exactly for this reason” the primary reasons for performing their job.

3.2.4 | Occupational commitment

Three items adapted from Meyer et al. (1993) were used to assess affective occupational commitment (T1 $\alpha = .85$; T2 $\alpha = .78$). A sample item is “The nursing profession means a lot to me”. Each item was scored on a five-point scale from “strongly disagree” to “strongly agree”.

3.2.5 | Occupational turnover intention

Three items adapted from O’Driscoll and Beehr (1994) were used to assess occupational turnover intention (T1 $\alpha = .88$; T2 $\alpha = .93$). A sample item is “I’m thinking about leaving the nursing profession”. Each item was scored on a seven-point scale from “strongly disagree” to “strongly agree”.

3.3 | Statistical analysis

A series of models were tested through structural equation modeling using a robust maximum likelihood estimator (MLR) in Mplus 8.4 (Muthén & Muthén, 2019). Full Information Maximum Likelihood (FIML) was used to handle missing data (e.g., Enders, 2010). To determine the goodness-of-fit of these models, various fit indices were used: The Comparative Fit Index (CFI), the Tucker-Lewis Index (TLI) and the Root Mean Square Error of Approximation (RMSEA). Values greater than .90 for the CFI and TLI and smaller than .08 for the RMSEA indicate acceptable fit (Marsh et al., 2005).

4 | RESULTS

4.1 | Preliminary analysis

Three measurement models were tested. The first model (M1a) consisted of all latent variables and indicators at Time 1 (supervisor and

coworker behaviours, autonomous motivation and occupational commitment and turnover intention), while the second model (M1b) included all latent variables and indicators at Time 2 (autonomous motivation and occupational commitment and turnover intention). Both models presented satisfactory fit indices: $\chi^2 (df) = 427.735 (199)$, CFI = .923, TLI = .911 and RMSEA = .062 [.054; .070] for Model 1a; and $\chi^2 (df) = 109.530 (51)$, CFI = .946, TLI = .930 and RMSEA = .066 [.049; .084] for Model 1b. A third measurement model was tested (M1c) by combining all latent variables and indicators at both measurement times and consisted of eight latent variables

(i.e., autonomous motivation and occupational commitment and turnover intention at Times 1 and 2, as well as supervisor and coworker behaviours at Time 1 only) and 34 indicators. Following previous recommendations (Little et al., 2007), each item at Time 1 was also allowed to covary with its corresponding item at Time 2. Results indicated that this model presented a satisfactory fit to the data: χ^2 (df) = 851.693 (487), CFI = .926, TLI = .915 and RMSEA = .044 [.039; .049]. Parameter estimates are reported in Table 1 (latent correlations) and Table 2 (loadings and uniqueness).

4.2 | Main analysis

The proposed model (see Figure 1) presented satisfactory fit to the data: χ^2 (df) = 895.721 (499), CFI = .919, TLI = .909 and RMSEA = .045 [.041; .050]. Supportive supervisor ($\beta = .162$, $p < .05$) and coworker ($\beta = .465$, $p < .001$) behaviours at Time 1 positively predicted autonomous motivation at Time 1. In addition, each of the following variables at Time 1 (autonomous motivation and occupational commitment and turnover intention) were significantly and positively related to its corresponding variable at Time 2 (β s ranging from .445 to .760, $p < .001$). Finally, results show that controlling for baseline effects, autonomous motivation at Time 1 positively predicted occupational commitment at Time 2 ($\beta = .232$, $p < .01$) and negatively predicted occupational turnover intention at Time 2 ($\beta = -.200$, $p < .05$).

Bootstrapping analyses (Cheung & Lau, 2008) were then conducted to analyze the mediating role of autonomous motivation at

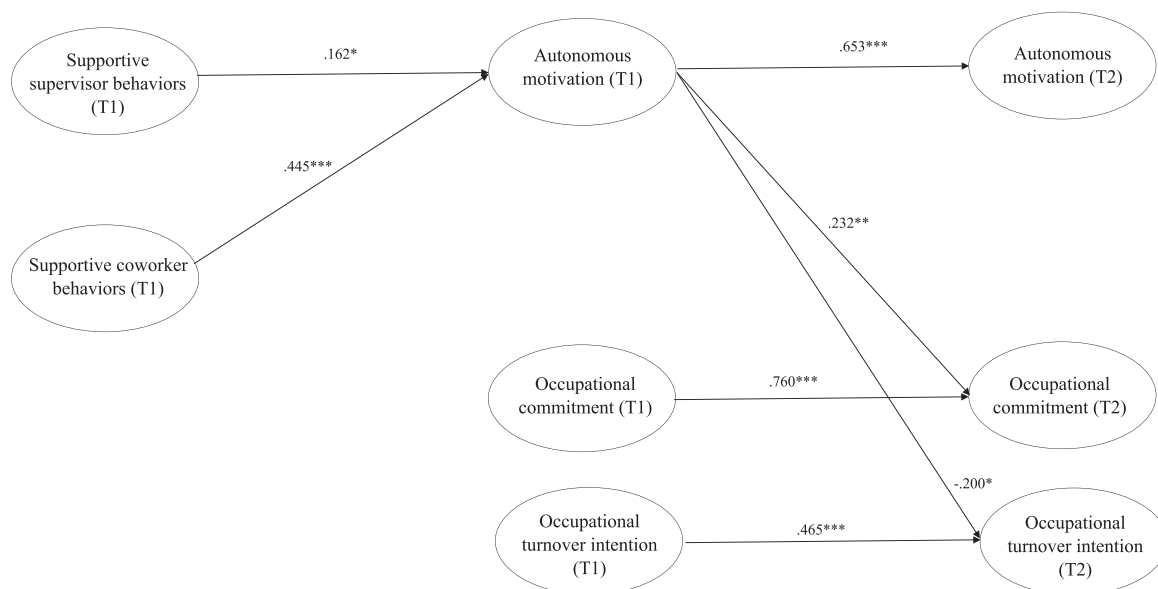

Time 1 in the relationships, on the one hand, between supportive supervisor and coworker behaviours at Time 1, and on the other hand, occupational commitment and turnover intention at Time 2. The indirect effects were tested with 95% confidence intervals computed from 5,000 bootstrap samples. First, the relationship between supportive supervisor behaviours at Time 1 and both outcomes at Time 2 was mediated by autonomous motivation at Time 1 (occupational commitment [indirect effect = .069; S.E. = .043; 95% CI = .007 to .183] and turnover intention [indirect effect = $-.038$; S.E. = .027; 95% CI = $-.122$ to $-.004$]). Second, the relationship between supportive coworker behaviours at Time 1 and both outcomes at Time 2 was mediated by autonomous motivation at Time 1 (occupational commitment [indirect effect = .199; S.E. = .089; 95% CI = .055 to .403] and turnover intention [direct effect = $-.109$; S.E. = .067; 95% CI = $-.293$ to $-.012$]).

5 | DISCUSSION

5.1 | Theoretical implications

The main contribution of this study is the identification of autonomous motivation as a dynamic individual factor that simultaneously acts on occupational commitment and turnover intention. The greater autonomous motivation the nurses show—investing in their work for pleasure and satisfaction or to achieve professional goals that they value—the more they will become affectively committed to their occupation and the less inclined they will be to leave it over time.

The Final Model

Note. * $p < .05$, ** $p < .01$, *** $p < .001$; for clarity purposes, covariances and indicators of latent variables are not presented.

FIGURE 1 The final model. * $p < .05$, ** $p < .01$, *** $p < .001$; for clarity purposes, covariances and indicators of latent variables are not presented

While these results align with those of recent cross-sectional studies carried out within the nursing context (Fernet et al., 2017; Galletta et al., 2019), they could constitute the first empirical evidence that nurses' autonomous motivation acts on occupational commitment and turnover intention over time.

The present study also sheds new light on the predictors and occupational outcomes of nurses' autonomous motivation. First, our results show that supportive behaviours by both the immediate supervisor and coworkers relate to nurses' work autonomous motivation. By revealing the distinct and complementary contribution of these key agents in their environment, our results underline the need to consider the role of social resources separately (rather than as an aggregate variable, irrespective of the source; e.g., supervisor, coworkers). These findings lend additional support to recent Job Demands-Resources model based-studies having shown the relative contribution of various job resources (Hakanen et al., 2021), including social support from the supervisor and coworkers in nursing studies (e.g., Van der Heijden et al., 2018). Whereas SDT-based research has heavily focused on supervisor behaviours, our results also invite to examine the contribution, not only of the immediate supervisor, but of other key agents in the work environment. Interestingly, the present findings are aligned with a recent experimental study (Jungert et al., 2021) showing that autonomy-supportive behaviours from coworkers increased autonomous motivation more than from a supervisor in a social occupational context.

5.2 | Limitations

First, the study relies exclusively on self-report data that may be subject to self-presentation report bias. Future research integrating multisource (e.g., coworker leadership assessment) and objective (e.g., actual turnover) data would increase the range of the results. Second, the study is based on a partial longitudinal design, which does not allow us to establish causal relationships between all the variables examined. Third, although we have relied on proven theoretical perspectives to determine predictors of autonomous motivation, our analysis relies on a limited set of predictors. Further research should enhance our understanding of predictors, especially the larger work environment, at various levels (e.g., organizational culture and climate, human resource practices). Finally, our study should be replicated in other countries with more heterogeneous samples (e.g., wider age range, racial and ethnic groups).

5.3 | Implications for nursing management

From a social perspective, keeping nurses in the profession is a major concern given the current global shortage, but also in terms of associated societal issues (Duffield et al., 2014). The COVID-19 pandemic context reminds us on the need to count on an adequate influx of healthcare personnel in order to maintain the efficiency of our healthcare systems. What emerges from our results is that nurses' occupational affective commitment (and the desire not to abandon it)

can be cultivated within an establishment by certain key agents, for example through the supportive nature of relationships with the immediate supervisor and coworkers. Organizational efforts to strengthen nurses' autonomous motivation, through supportive supervisor and coworker behaviours, should prove to be a beneficial strategy for contributing to a well-rooted workforce in the profession.

Among the possible means to facilitate such efforts, healthcare managers, including supervisors in departments or units, could promote a culture of support, for example by encouraging equity in the application of policies and relying on shared leadership (Pursio et al., 2021). The finding that supportive coworker behaviours would be particularly important to facilitate nurses' autonomous motivation adds to the relevance of bringing particular attention to shared leadership in which team members with particular knowledge, skills or abilities assume greater leadership in some areas of their work. Coaching activities, as well as formal and informal mentoring, may also help to build a more supportive workplace climate for nurses (Newman et al., 2012). SDT has great potential in this regard, particularly for understanding the need-supportive conditions (e.g., autonomy support, appropriate structure and interpersonal involvement strategies) that facilitate optimal functioning and might therefore serve as an impetus to increase the scope of such activities. In parallel, organizational interventions could be developed to raise awareness of nurses' autonomous motivation. Van Dorssen-Boog et al. (2021) recently provided evidence that the implementation of a self-leadership training program (based on motivation principles such as mastery, proactive problem-solving, and strength-based coaching) facilitates healthcare employees' autonomous motivation and fosters their work engagement and performance. Future interventions efforts along these lines are encouraged as they offer promising avenues to foster high quality work motivation and subsequently occupational commitment and retention in nurses.
